

Typology of programming languages

~ Return Statement ~

Return Statement

What is the purpose of the return statement?

Is there a best way to return something?

Is there a best way to return something?

Table of Contents

- 1 Return via dedicated keyword
- 2 Return via function's name
- 3 Return via specific variable
- 4 Return the last computed value
- 5 Named return values
- 6 Return from a block

Return via a dedicated keyword 1/2

```
int compute(int a, int b) {  
    int res = a+b;  
    // Some computation  
    return res;  
}
```

C's return statement uses the **return** keyword

```
int compute(int a, int b) {  
    int r_val = a+b;  
    // Some computation  
    return r_val;  
}
```

Java's return statement also uses the **return** keyword

Return via a dedicated keyword 2/2

The **return** statement breaks the current function (also for C++, Java, Ada, Modula2).

- Clarity
- Complexify the code
 - ▶ No naming convention
 - ▶ No homogeneous return inside a given function
 - ▶ Blur the comprehension via initialisation, intermediate computation, ...

Table of Contents

- 1 Return via dedicated keyword
- 2 Return via function's name**
- 3 Return via specific variable
- 4 Return the last computed value
- 5 Named return values
- 6 Return from a block

Return via function's name (1/2)

```
function sum (a, b: integer)
    : integer;
begin
    sum := a + b;
end;
```

Pascal's return statement uses the name of the function

Return via function's name (2/2)

The name of the function is treated as a variable name (also for Fortran, ALGOL, ALGOL68, Simula)

- The “return” may not be the latest statement
- **Ambiguous**
 - ▶ For recursion **sum** denotes a variable **AND** a function
 - ▶ Is *somevar := sum* legal? (Yes for Pascal, No for Fortan)

Table of Contents

- 1 Return via dedicated keyword
- 2 Return via function's name
- 3 Return via specific variable**
- 4 Return the last computed value
- 5 Named return values
- 6 Return from a block

Return via a specific variable (1/2)

```
always_true : BOOLEAN  
do  
  Result := true  
end
```

```
always_one : INTEGER  
do  
  Result := 1  
end
```

```
always_bar : STRING  
do  
  Result := "bar"  
end
```

Effeil's return statement uses the keyword **Result**

Return via a specific variable (2/2)

- The value returned by a function is whatever value is in **Result** when the function ends.
- The return value of a feature is set by assigning it to the **Result** variable (initialised automatically to a default value).
- Unlike other languages, the **return** statement does not exist.

Only in Eiffel (to my knowledge)

- Clarity
- Ambiguous if the language support nested functions

Table of Contents

- 1 Return via dedicated keyword
- 2 Return via function's name
- 3 Return via specific variable
- 4 Return the last computed value**
- 5 Named return values
- 6 Return from a block

Return the last computed value 1 / 2

```
(defun double (x) (* x 2))
```

Lisp's return value is the last computed

```
fn is_divisible_by(lhs: u32,
                   rhs: u32)
    -> bool {
    if rhs == 0 {
        return false;
    }
    // The `return` keyword
    // isn't necessary
    lhs % rhs == 0
}
```

Same for **Rust's return value**

Return the last computed value 2 / 2

In **expression-oriented programming language** (also Lisp, Perl, Javascript and Ruby) the return statement can be omitted.

- **Instead that the last evaluated expression is the return value.**
- A "last expression" is mandatory in Rust
- If no "return" Python returns **None** and Javascript **undefined**

Table of Contents

- 1 Return via dedicated keyword
- 2 Return via function's name
- 3 Return via specific variable
- 4 Return the last computed value
- 5 Named return values**
- 6 Return from a block

Named return values and Naked return

```
func make(r int, i int)
    (re int, im int) {
    re = r
    im = i
    return
}
```

Go combines Named returns values and naked return

Named return values and Naked return

- No declaration/initialisation in the body of the function
- It serves as documentation.

- Functions that return multiple values are hard to name clearly
GetUsernameAndPassword
- The signature of the function is slightly more difficult to read

Table of Contents

- 1 Return via dedicated keyword
- 2 Return via function's name
- 3 Return via specific variable
- 4 Return the last computed value
- 5 Named return values
- 6 Return from a block**

return-from

return-from in lisp

```
(block alpha  
  (return-from alpha 1) 2)
```

- Provide a structured lexical non-local exit facility
- Faster than a try-catch (also developed by Lisp with errorset or PL/I)

Summary

dedicated
keyword

Function
name

Specific
variable

Last
computed

From a
block

Named
return val.
