Abstract—This paper describes the solver P-MCOMSPS-STR submitted to the parallel track of the 2020’s SAT Competition. It is a concurrent portfolio solver instantiated with the Painless (PArallel INSTantiable Sat Solver) framework and using MapleCOMSPS as core sequential solver.

I. INTRODUCTION

P-MCOMSPS-STR is a parallel SAT solvers built by instantiating components of the Painless parallel framework [1]. It is a portfolio-based [2] solver implementing a diversification strategy [3], fine control of learnt clause exchanges [4], using MapleCOMSPS [5] as a core sequential solver, and where learnt clause strengthening [6] has been integrated.

Section II gives an overview on Painless framework. Section III details the implementation of P-MCOMSPS-STR using Painless and MapleCOMSPS.

II. DESCRIPTION OF PAINLESS

Painless is a framework that aims at simplifying the implementation and evaluation of parallel SAT solvers for many-core environments. Thanks to its genericity and modularity, the components of Painless can be instantiated independently to produce new complete solvers.

The main idea of the framework is to separate the technical components (e.g., those dedicated to the management of concurrent programming aspects) from those implementing heuristics and optimizations embedded in a parallel SAT solver. Hence, the developer of a (new) parallel solver concentrates his efforts on the functional aspects, namely parallelization and sharing strategies, thus delegating implementation issues (e.g., data concurrent access protection mechanisms) to the framework.

Three main components arise when treating parallel SAT solvers: sequential engines, parallelization, and sharing. These form the global architecture of Painless.

A. Sequential Engines

The core element that we consider in our framework is a sequential SAT solver. This can be any CDCL state-of-the-art solver. Technically, these engines are operated through a generic interface providing basics of sequential solvers: solve, interrupt, add clauses, etc.

Thus, to instantiate Painless with a particular solver, one needs to implement the interface according this engine.

B. Parallelization

To built a parallel solver using the aforementioned engines, one needs to define and implement a parallelization strategy. Portfolio and Divide-and-Conquer are the basic known ones. Also, they can be arbitrary composed to form new strategies.

In Painless, a strategy is represented by a tree-structure of arbitrary depth. The internal nodes of the tree represent parallelization strategies, and leaves are core engines. Technically, the internal nodes are implemented using WorkingStrategy component and the leaves are instances of SequentialWorker component.

Hence, to develop its own parallelization strategy, the user should create one or more strategies, and build the associated tree-structure.

C. Sharing

In parallel SAT solving, the exchange of learnt clauses warrants a particular focus. Indeed, beside the theoretical aspects, a bad implementation of a good sharing strategy may dramatically impact the solver’s efficiency.

In Painless, solvers can export (import) clauses to (from) the others during the resolution process. Technically, this is done by using lock-free queues [7]. The sharing of these learnt clauses is dedicated to particular components called Sharers. Each Sharer is in charge of sets of producers and consumers and its behaviour reduces to a loop of sleeping and exchange phases.

Hence, the only part requiring a particular implementation is the exchange phase, that is user defined.

III. P-MCOMSPS-STR

This section describes the overall behaviour of our competing instantiation named P-MCOMSPS-STR. Its architecture is highlighted in Fig. 1. It implements the Painless strengthening described in [8]. In the following, we highlight the outline.

A. MapleCOMPS

MapleCOMPS [5] is based on MiniSat [9], and relies on the classical VSIDS [10], and the more recently defined LRB [11] for its decision heuristics. These two are used in one-shot phases: first LRB, then VSIDS. Moreover, it uses Gaussian Elimination (GE) at preprocessing time.
Every 1.5 seconds, 1500 literals (the exports clauses having a LBD value under a given threshold) are dispatched to consumers. The LBD threshold of the concerned solver is increased (resp. decreased) if an insufficient (resp. too big) number of literals are dispatched: respectively, less than 75% (1125 literals) and more than 98% (1470 literals).

E. Online Strengthening

The reducer engine is both a consumer and a producer of the sharer (Shr). It receives clauses from the different cores, strengthened them, in case of success it then exports them back. The sharing mechanism will then share this strengthened clauses to all the other solvers.

Since, a strengthened clause subsumes the original one, it is likely that cores will forget the original clause over time.

ACKNOWLEDGMENT

We would like to thank Jia Hui Liang, Chanseok Oh, Vijay Ganesh, Krzysztof Czarnecki, and Pascal Poupart, the authors of MapleCOMSPS.
