

Some Elements of C++ 2011

Roland Levillain

EPITA Research and Development Laboratory (LRDE)

2012

Outline

- 1 `nullptr`
- 2 Consecutive Right Angle Brackets (>>) in Templates
- 3 New Type Alias Syntax and Alias Templates
- 4 Initializer Lists and Generalized Initialization Syntax
- 5 Range-Based `for` Loops
- 6 `auto`-Typed Variables
- 7 Defaulted and Deleted Functions

Literal null pointer

- Null pointer in C++ 1998/2003 : 0 (not NULL)
- 0 is also the zero literal (constant).
- Overloading ambiguities:

```
void foo(short i);  
void foo(float* p);  
  
int main() {  
    foo(0); // foo(short) or foo(float*)?  
}
```

- New C++ 2011 keyword: **nullptr**: null pointer literal.
- Ambiguity solved:

```
foo(nullptr);
```

Simplifying Nested Templates

- In C++ 1998/2003, this code is not valid:

```
| std :: vector<std :: pair<int , float>> v ;
```

- The '>>' is seen as 'operator>>'
- Valid syntax:

```
| std :: vector< std :: pair<int , float> > v ;
```

- New interpretation in C++ 2011: '>>' are two closing angle brackets.

New type-related uses of `using`

- Defining a type alias (typedef) in C++ 1998/2003:

```
typedef std::list<std::string> stringlist;
typedef int (*intfun)(int);
```

- Alternative syntax in C++ 2011:

```
using stringlist = std::list<std::string>;
using intfun = int (*)(int);
```

- `using` statements can be parameterized:

```
template<unsigned n, typename T>
class vec;
```

```
template<typename T>
using triplet = vec<3, T>;
```

Shortening Initializations

- Initializing containers is sometimes cumbersome:

```
std::list<int> values;  
values.push_back (1);  
values.push_back (2);  
values.push_back (3);  
// ...
```

- C++ 2011 extends the C array initialization syntax to any container:

```
std::list<int> values = { 1, 2, 3, 4, 5 };
```

or

```
std::list<int> values { 1, 2, 3, 4, 5 };
```

Constructing with an Initializer List

- These *initializer lists* are passed as

```
| std::initializer_list<T>
```

objects.

- New category of constructor:

```
| container<T>::container (std::initializer_list<T> l)  
{  
|   insert (begin (), l.begin (), l.end ());  
| }  
}
```

Shortening and Generalizing Iterations on Containers

- Classic iterator-based traversal:

```
std::list<int> values = { 1, 2, 3, 4, 5 };  
int sum = 0;  
for (std::list<int>::const_iterator i = values.begin();  
     i != values.end(); ++i)  
    sum += *i;
```

- Foreach-like C++ 2011 syntactic sugar:

```
int sum = 0;  
for (const int& i : values)  
    sum += i;
```

Extensibility of Range-Based for Loops

- Also works with non class-based containers:

```
int values[5] = {1, 2, 3, 4, 5};  
int sum = 0;  
for (const int& i : values)  
    sum += i;
```

- Mechanism based on *non-member* `begin()` and `end()` functions.
- Can be extended to any type `T`, by adding the following new functions, returning `const` (resp. `mutable`) iterators:
 - `begin(const T&)` (resp. `begin(T&)`)
 - `end(const T&)` (resp. `end(T&)`)

Automatic Type Deduction

- C++ can be verbose:

```
std::map<int, std::string>* dict =
    new std::map<int, std::string>;
very_long_type<int, float, double> v = foo (42);
```

- New C++ 2011 keyword for automatic type deduction : **auto** (actually, not really new).

```
auto dict = new std::map<float, std::string>;
auto v = foo (42);
```

- Can be **const**-qualified and used with '&':

```
const auto& w = bar (51);
```

Changing the Default Behavior of the Compiler

- Making a type non-copyable and not directly constructible:

```
class Foo
{
private:
    Foo (const Foo&);           // Only declared.
    Foo & operator= (const Foo&); // Only declared.

    Foo ();

public:
    static const Foo& instance ();
};

Foo::Foo () {}
const Foo& Foo::Foo& instance () { static Foo f; return f; }
```

Changing the Default Behavior of the Compiler

- In C++ 2011, with keywords **default** and **delete**:

```
class Foo
{
    Foo (const Foo&) = delete;
    Foo & operator= (const Foo&) = delete;

public:
    static const Foo& instance ();

private:
    Foo() = default;
};

const Foo& Foo::Foo& instance () { static Foo f; return f; }
```
